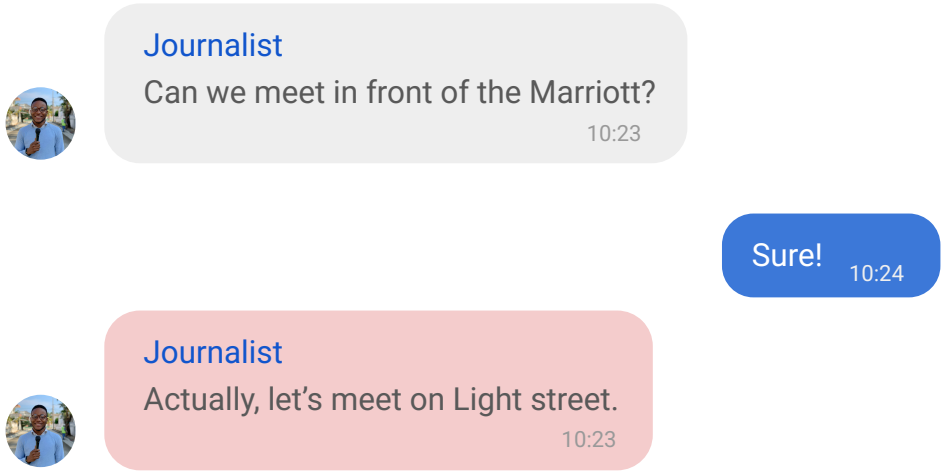
Our Contributions

Two attacks that allow a malicious server to inject arbitrary messages in a conversation, undetected

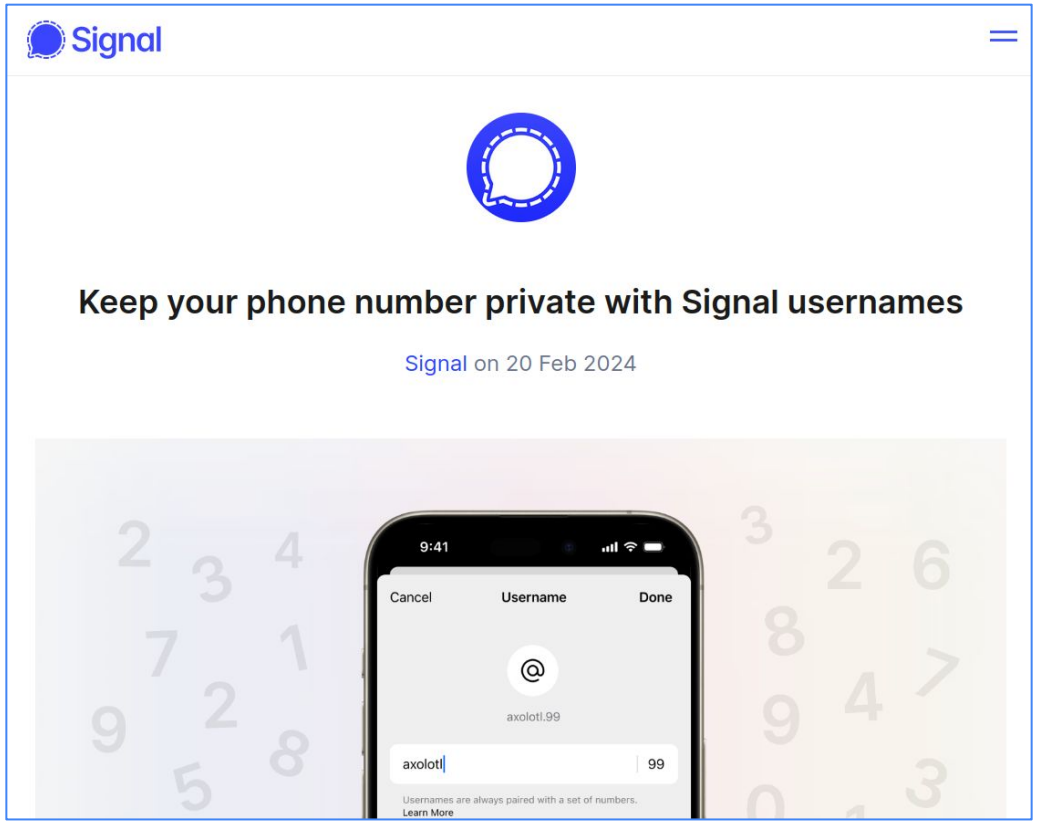
and

Detailed descriptions of protocols that were never analyzed and that affect the security of conversations in Signal.

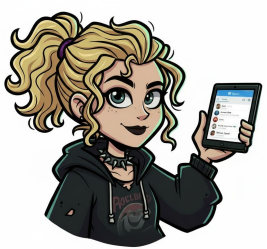


Attack 1: Usernames and Session Handling

Introduction of usernames in Signal



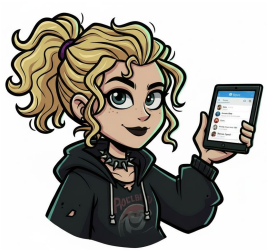
Phone Numbers vs Usernames

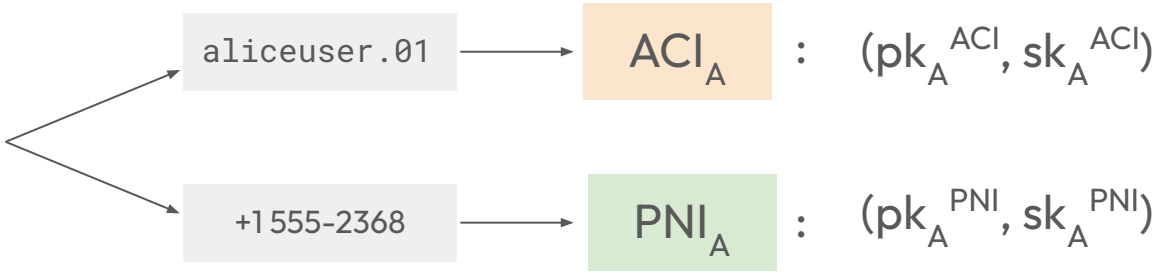


+1 555-2368 → PNI_A : (pk_A^{PNI}, sk_A^{PNI})

PNI: Phone Number Identifier

Phone Numbers vs Usernames

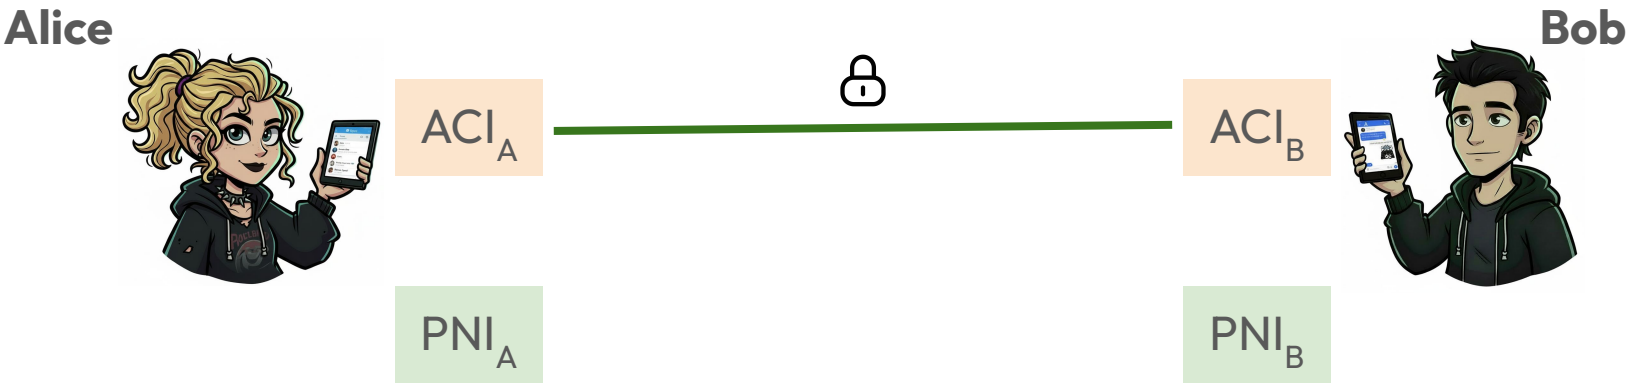




PNI: Phone Number Identifier

ACI: Account Identifier

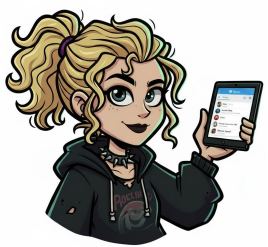
ACIs, PNIs and sessions



ACI_A — ACI_B session: by username

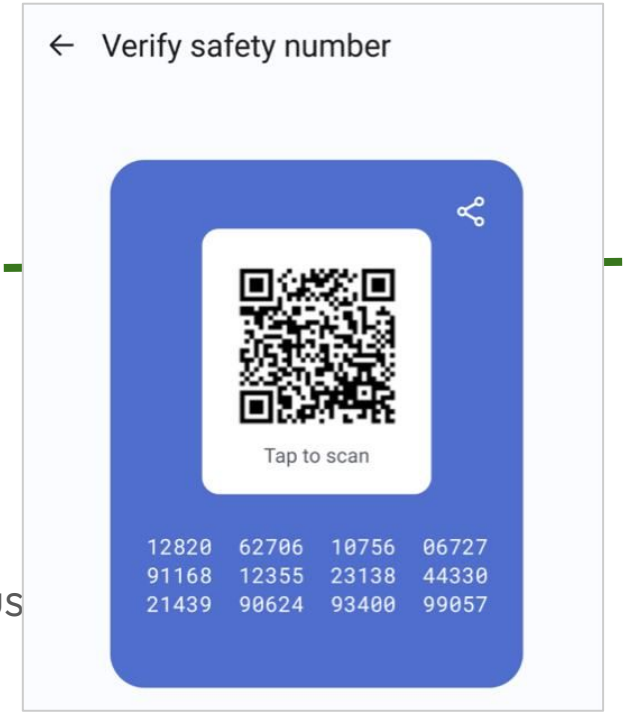
ACIs, PNIs and sessions

Alice



ACI_A

PNI_A



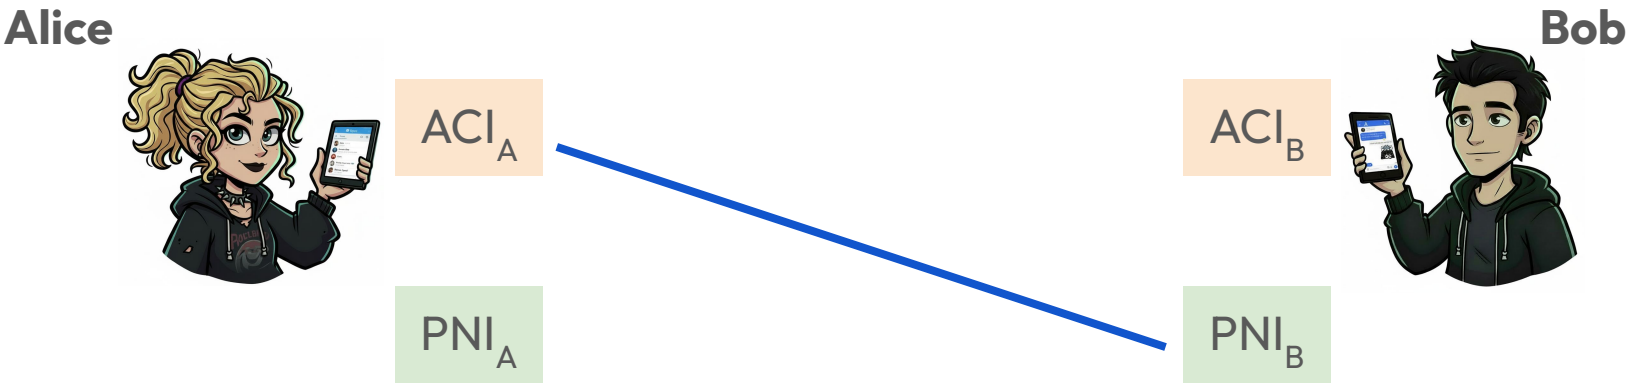
ACI_B

PNI_B

Bob

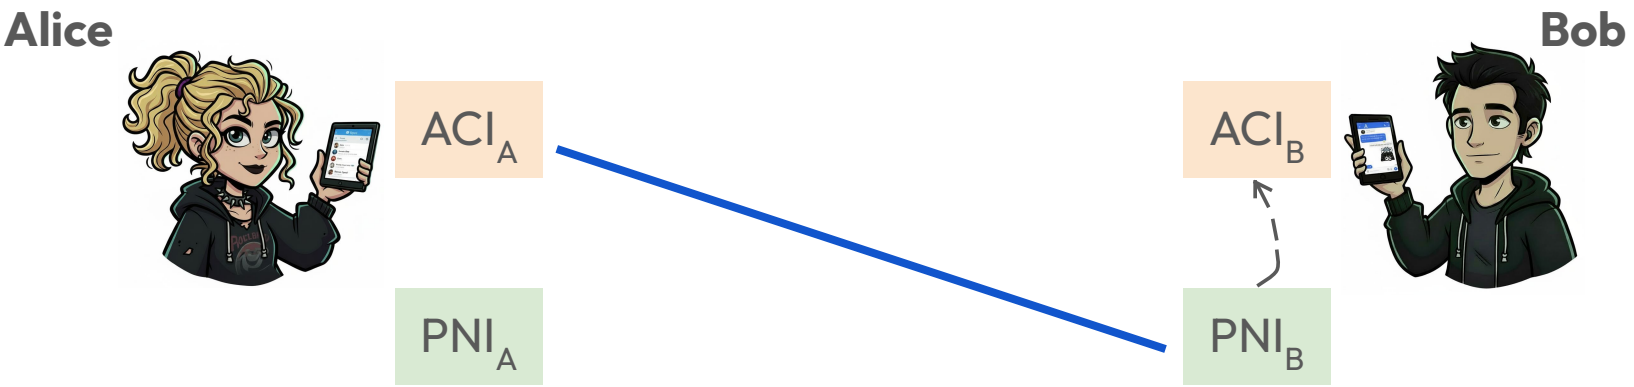
ACI_A — ACI_B session: by us

ACIs, PNIs and sessions



ACI_A — PNI_B session: by phone number

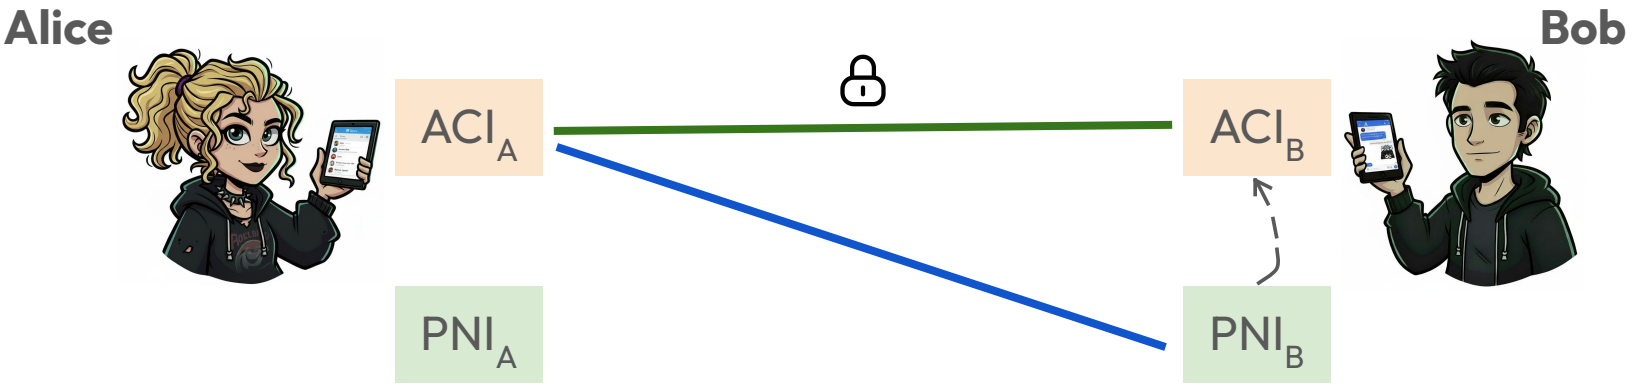
ACIs, PNIs and sessions



ACI_A — PNI_B session: by phone number

upgrade to ACI...

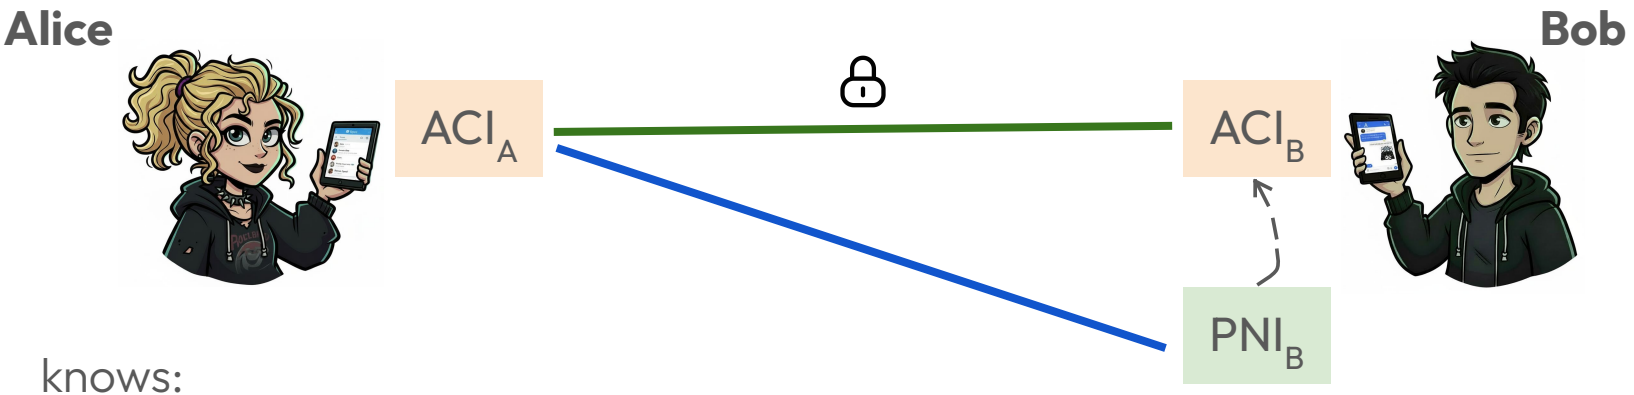
ACIs, PNIs and sessions



ACI$_A$ — PNI$_B$ session: by phone number

upgrade to ACI... new ACI$_A$ — ACI$_B$ session!

“PNI-to-ACI” protocol



knows:

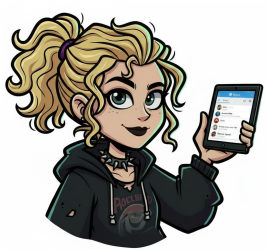
PNI_B , pk_B^{PNI}

merges ACI_B, pk_B^{ACI}, PNI_B, pk_B^{PNI}

signs pk_B^{ACI} with sk_B^{PNI}

Involved protocols: X3DH, Double Ratchet, Sesame

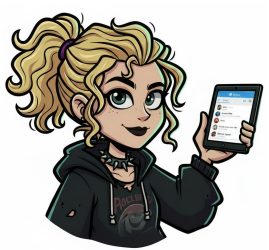
“PNI-to-ACI” protocol

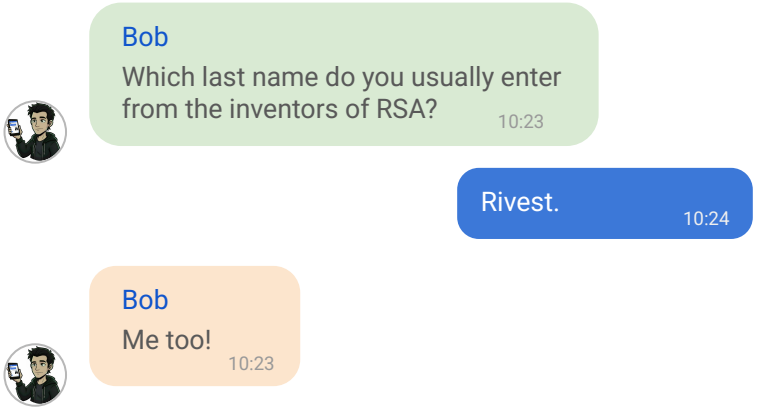


…	…	…	…	…	…
+1 555-1259	bobsignal.03	PNI_B	pk_B^{PNI}	ACI_B	pk_B^{ACI}
NULL	charlie.42	NULL	NULL	ACI_C	pk_C^{ACI}
…	…	…	…	…	…

The two identities are not cryptographically linked:
they are merged into the same database row.

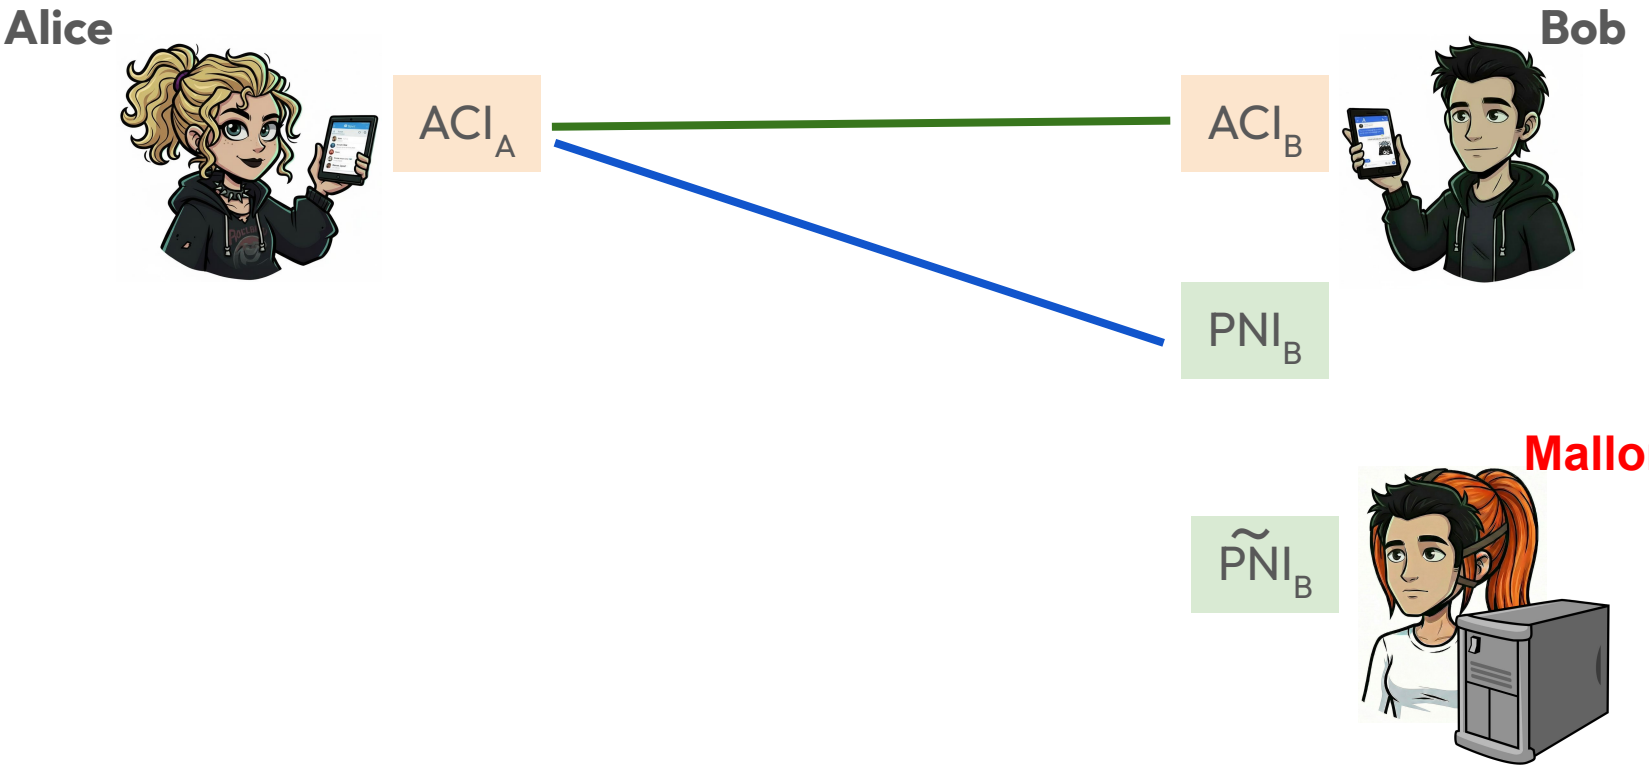
“PNI-to-ACI” protocol



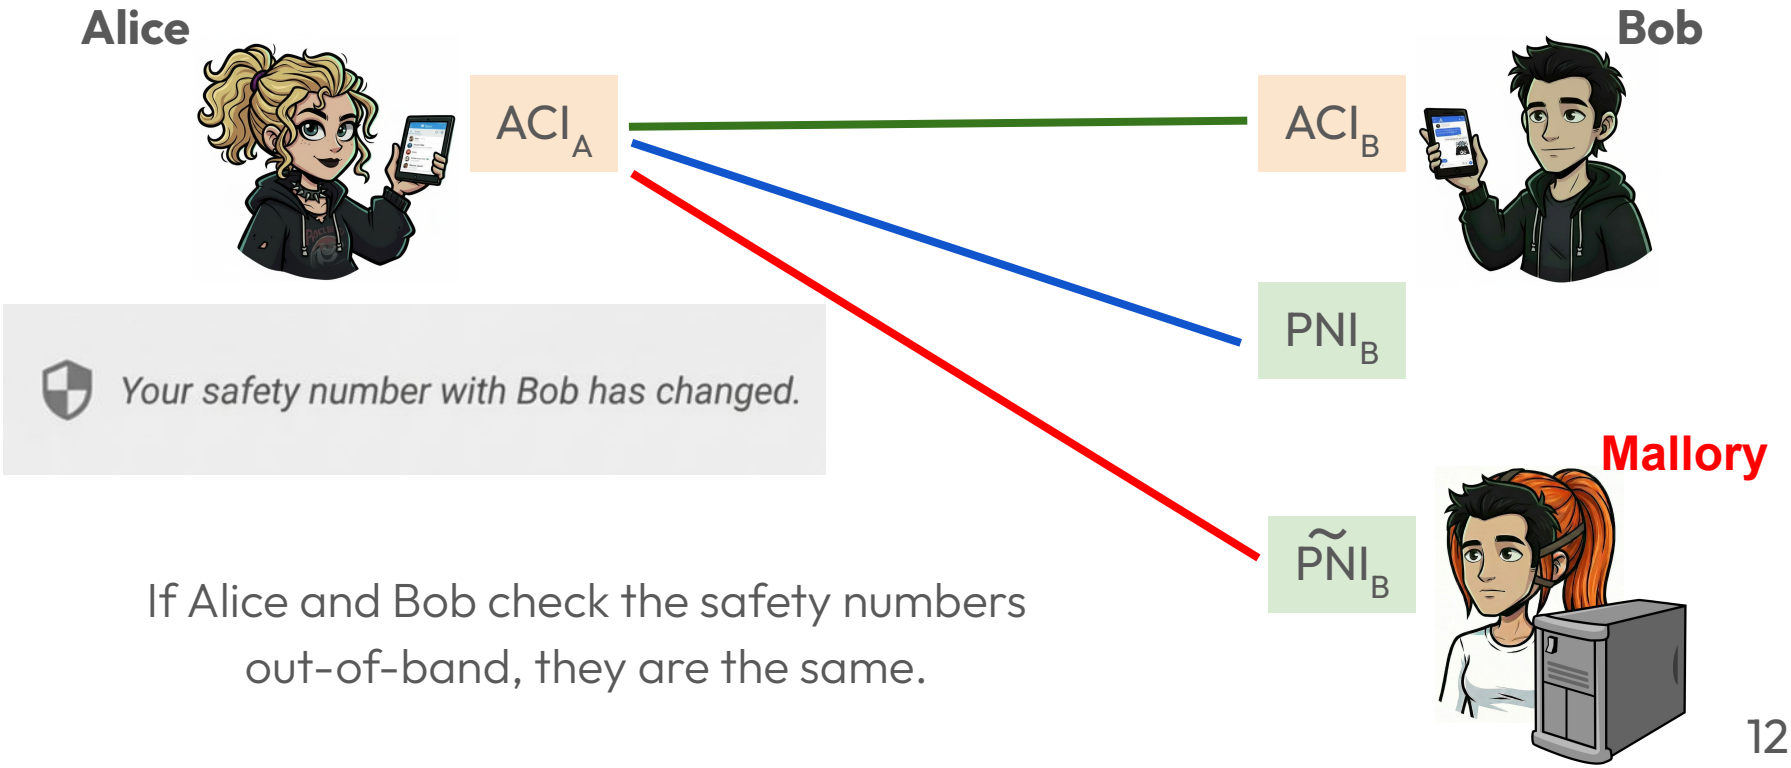


After linking, any message with PNI_B or ACI_B as a source will be **displayed in the same conversation.**

The First Attack

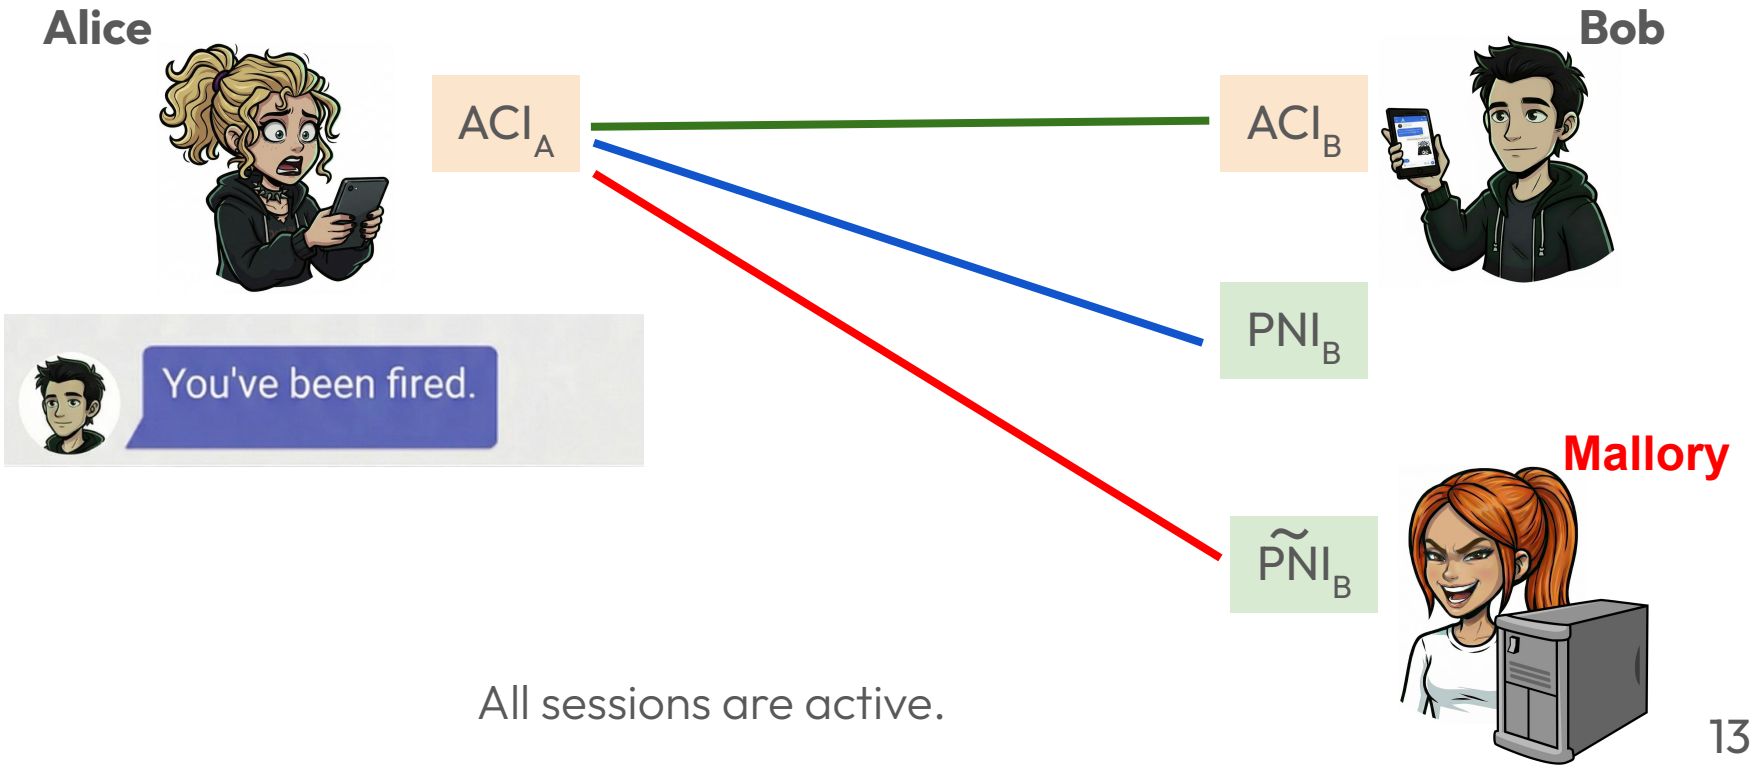


The First Attack



If Alice and Bob check the safety numbers out-of-band, they are the same.

The First Attack



All sessions are active.

Attack 2: Sealed Sender and Plaintext Messages

Injecting Messages

In Signal, a malicious server can send a message on behalf of anyone, as the sender field is not authenticated...

...but it cannot forge valid ciphertexts!

Injecting Messages

Plaintext content is allowed, but only to **encode errors.**

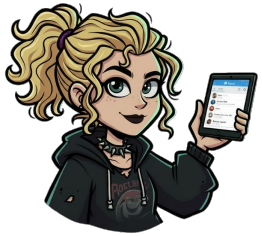
Issue 1: Sealed Sender does not authenticate

The Signal server signs (pk_A, ACI_A) to certify the association

pk_A

Reveals the sender identity to Bob

pk_B



$PKE.Enc(pk_B, msg=pk_A||ACI_A||cert)$

$AuthPKE.Enc(pk_B, sender\_pk=pk_A, msg=m)$

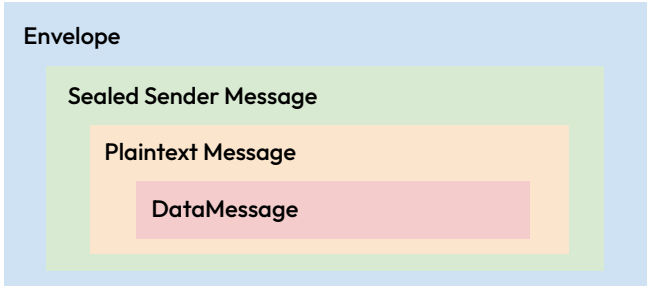
Wraps m and ensures it was sent by Alice

Wants to wrap msg m

Unfortunately, cert doesn't provide much if the server is malicious…

A malicious server can send a message on behalf of **anyone**.

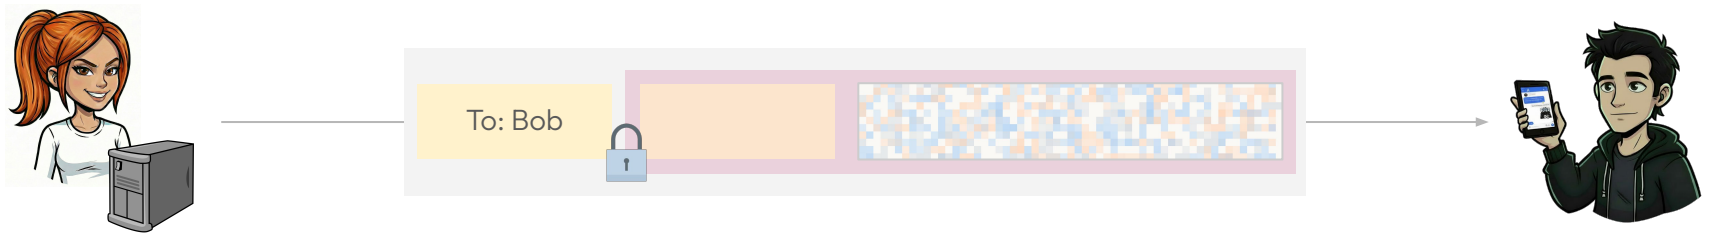
Issue 2: Sealed Sender does not validate plaintext content



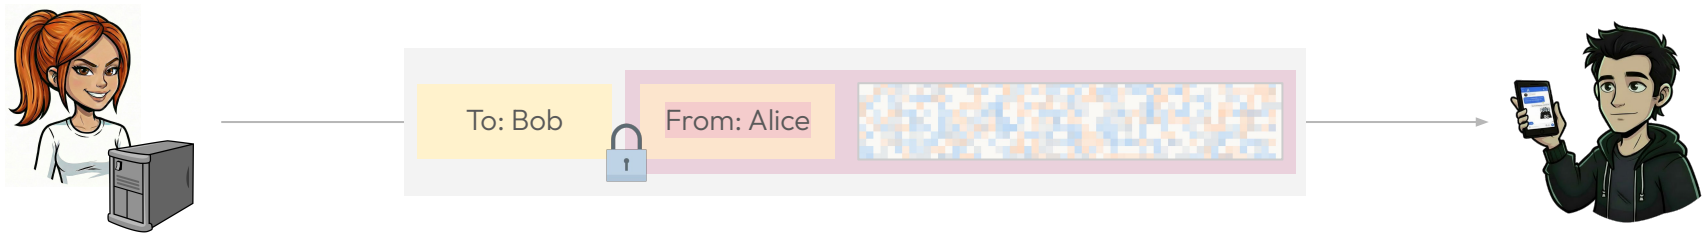
...due to **incorrect validation**, plaintext content for text messages is accepted if using Sealed Sender.

A malicious server can inject **arbitrary messages**.

Combining the Two Issues



Combining the Two Issues



The server can send messages as any user…

Combining the Two Issues

The server can send messages as any user…

… and send plaintext content, bypassing authentication!

Conclusions

Signal is an app...

Its cryptography should be studied at the system level

Signal

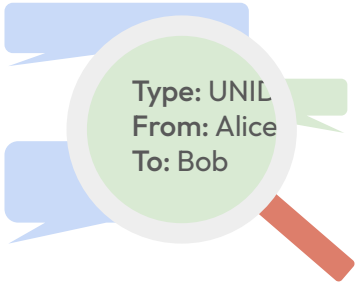
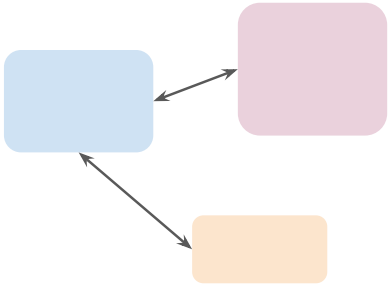
The Sesame Algorithm: Session Management for Asynchronous Message Encryption

Could we have spotted this earlier?

Formal analyses *could* have spotted these attacks...



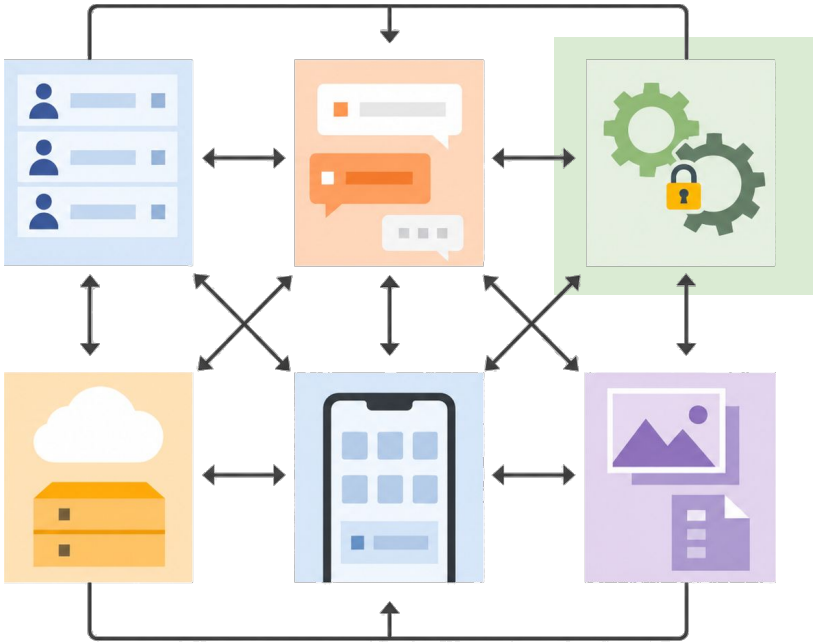
...but only if they captured the system in enough detail



...and only if they captured the interaction between all protocols

...but our techniques do not seem mature enough to capture this level of complexity yet.

For vendors



There's no such thing as a cryptographic core. Everything in the application is security-relevant.

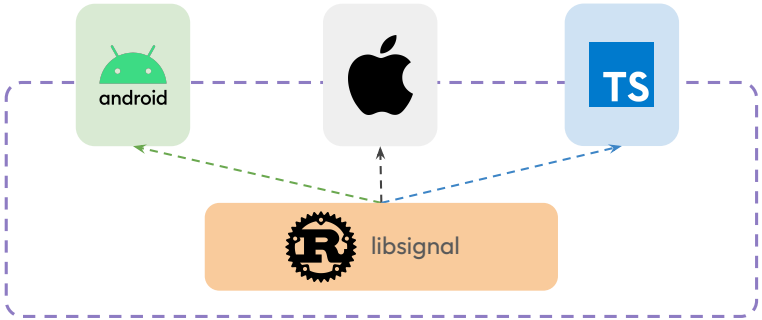
Audit your cryptography and the rest of your code together.

Platform-Dependent Logic

Attack 1 affects Android and Desktop.

Attack 2 affects only Android.

Avoid scattering cryptographic logic across modules and platforms.



- We analysed Signal in the **malicious server setting.**
- We found **two attacks which violate conversation integrity.**
- Signal for iOS was unaffected by both attacks.
  Signal Desktop was unaffected by the second attack.
- Both attacks were **patched very quickly by the Signal team**, whom we thank for the smooth disclosure procedure.
